# MULTIPLIERS OF UNIFORM CONVERGENCE

# by Ronald DeVore

1. Introduction. If A and B are two classes of  $2\pi$ -periodic integrable functions we say that  $(\lambda_k)$  is a multiplier sequence from A into B and we write  $(\lambda_k) \in (A, B)$  if whenever

$$\sum_{0}^{\infty} \left( a_n \cos nx + b_n \sin nx \right)$$

is the Fourier series of a function in A

$$\sum_{0}^{\infty} \lambda_n (a_n \cos nx + b_n \sin nx)$$

is the Fourier series of a function in *B*. Let *C* denote the class of  $2\pi$ -periodic continuous functions and  $C_F$  the subclass of those functions in *C* whose Fourier series converges uniformly. Karamata [1] has shown that  $(\lambda_k) \in (C, C_F)$  if and only if

(1.1) 
$$\int_{0}^{2\pi} |\Lambda_{n}(t)| dt = O(1) \quad (n \to \infty)$$

where

$$\Lambda_n(t) = \sum_{0}^n \lambda_k \cos kt.$$

This theorem contains as a special case an earlier result of Tomić [2] who showed that if  $(\lambda_k)$  is monotone decreasing and convex (i.e.  $\Delta^2 \lambda_k =$  $\lambda_k - 2\lambda_{k-1} + \lambda_{k-2} \ge 0$ ) or more generally quasi-convex (i.e.  $\sum_{0}^{\infty} (k+1) |\Delta^2 \lambda_k|$  $<\infty$ ) then  $(\lambda_k) \in (C, C_F)$  if and only if  $\lambda_n \log n = O(1)$   $(n \to \infty)$ .

It is interesting to see to what extent condition (1.1) can be relaxed if we restrict our attention to a sub-class of C determined by some structural property. For example, let  $\omega$  be a modulus of continuity and  $C_{\omega}$  the subclass of C consisting of those functions whose modulus of continuity  $\omega$  (f, h) satisfies

$$\omega(f,h) = O(\omega(h)) \quad (h \to 0).$$

Then Tomić [3] has shown that for a quasi-convex sequence  $(\lambda_k)$  to be in  $(C_{\omega}, C_F)$  it is sufficient that

(1.2) 
$$\omega\left(\frac{1}{n}\right)\lambda_n\log n = o(1) \quad (n \to \infty).$$

Also Bojanic [4] has shown that sufficient conditions for  $(\lambda_k)$  to be in  $(C_{\omega}, C_F)$  are

(1.3) 
$$\int_{0}^{2\pi} \left| \sum_{k=0}^{n} \Lambda_{k}(t) \right| dt = O(n) \quad (n \to \infty)$$

and

(1.4) 
$$\omega\left(\frac{1}{n}\right)\int_{0}^{2\pi}|\Lambda_{n}(t)|dt = o(1) \quad (n \to \infty).$$

Of course, condition (1.3) is equivalent to  $(\lambda_k)$  being a Fourier Stieljes sequence which in particular characterizes the class of multipliers (C, C).

No necessary conditions have been given for  $(\lambda_k)$  to be in  $(C_{\omega}, C_F)$  and sufficient conditions have been restricted to quasi-convex and Fourier-Stieljes sequences. In order to obtain necessary and sufficient conditions for  $(\lambda_k)$  to be in  $(C_{\omega}, C_F)$ , it is natural to attempt to make  $C_{\omega}$  a Banach space in which trigonometric polynomials are dense and then invoke the Banach-Steinhaus theorem as Karamata did in characterizing  $(C, C_F)$ . The most natural norm is to define for  $f \in C_{\omega}$ 

$$||f||_{\omega} = \max\left(||f||_{\infty}, \sup_{h>0} \frac{\omega(f,h)}{\omega(h)}\right)$$

where  $||f||_{\infty}$  is the usual supremum norm.

The normed space  $(C_{\omega}, ||\cdot||_{\omega})$  is a Banach space. However, trigonometric polynomials are not dense in  $(C_{\omega}, ||\cdot||_{\omega})$ . For if  $\omega(h) \neq O(h) (h \rightarrow 0)$ , then whenever  $(T_n)$  is a sequence of trigonometric polynomials which converge in  $||\cdot||_{\omega}$  to f, f satisfies

$$\omega(f,h) = o(\omega(h)) \quad (h \to 0).$$

In the case that  $\omega(h) = O(h)$   $(h \to 0)$ , then a sequence of trigonometric polynomials  $(T_n)$  converge in  $|| \cdot ||_{\omega}$  if and only both  $T_n$  an  $T'_n$  converge uniformly and therefore f is the limit of the sequence  $(T_n)$  only if f is contin-

— 177 —

uously differentiable. Accordingly, when  $\omega(h) \neq O(h) (h \rightarrow 0)$ , we define  $c_{\omega}$  as the class of those functions in  $C_{\omega}$  for which

$$\omega(f,h) = o(\omega(h)) \quad (h \to 0)$$

and when  $\omega(h) = O(h) (h \to 0)$  we define  $c_{\omega}$  as the class of all continuously differentiable functions.  $c_{\omega}$  is then a closed subspace of  $C_{\omega}$  and it is easy to see that if  $f \in c_{\omega}$ , the Fejer sums of f

$$\sigma_n(f) = \int_0^{2\pi} f(t) F_n(t-x) dt$$

with

$$F_n(t) = \frac{1}{2\pi (n+1)} \left( \frac{\sin (n+1)\frac{1}{2}t}{\sin \frac{1}{2}t} \right)^2$$

converges in  $\|\cdot\|_{\omega}$  to f. Thus,  $c_{\omega}$  is precisely the closure of the class of trigonometric polynomials in  $\|\cdot\|_{\omega}$ . It therefore appears some what more natural to consider the class  $c_{\omega}$  rather than the class  $C_{\omega}$  in terms of problems involving multiplier sequences. For we then have

PROPOSITION 1. The sequence 
$$(\lambda_k) \in (c_{\omega}, C_F)$$
 if and only if  
 $||| \Lambda_n |||_{\omega} \equiv \sup_{\substack{f \in c_{\omega} \\ ||f||_{\omega} \leq 1}} || \int_{0}^{2\pi} f(t) \Lambda_n (t-x) dt ||_{\infty} = O(1) \quad (n \to \infty)$ 

This is an immediate application of the Banach-Steinhaus theorem [5, p. 60] and the fact that the operators

$$L_{n}(f)(x) = \int_{0}^{2\pi} f(t) \Lambda_{n}(t-x) dt$$

converge in  $\|\cdot\|_{\infty}$  for each trigonometric polynomial T.

We shall find it convenient to use the following proposition which follows immediately from the fact that any function f in  $C_{\omega}$  with  $||f||_{\omega} \leq 1$  is the uniform limit of sequence of functions from the unit ball of  $(c_{\omega}, ||\cdot||_{\omega})$  (e.g.  $\sigma_n(f)$  provides such a sequence of functions).

**PROPOSITION 2.** If  $\Lambda$  (t) is an integrable function then

$$||| \Lambda |||_{\omega} = \sup_{\substack{f \in C_{\omega} \\ ||f||_{\omega} \leq 1}} || \int_{0}^{2\pi} f(t) \Lambda_{n}(t-x) dt ||_{\infty}$$

In section 2, we shall consider quasi-convex sequences and show that in this case  $(\lambda_k) \in (c_{\omega}, C_F)$  if and only if

$$\lambda_n \omega\left(\frac{1}{n}\right) \log n = O(1) \quad (n \to \infty).$$

In section 3, we shall give a necessary condition that  $(\lambda_k)$  be in  $(c_{\omega}, C_F)$  with no restrictions on  $(\lambda_k)$ . We shall show that  $(\lambda_k) \in (c_{\omega}, C_F)$  only if

$$\omega\left(\frac{1}{n}\right)\int_{0}^{2\pi} |\Lambda_{n}(t)| dt = O(1) \quad (n \to \infty).$$

It is easy to see that this condition is in general not sufficient. For example, if  $\omega(h) = h$ , then simple integration by parts (see theorem 4.2) shows that

$$|||\Lambda_{n}|||_{\omega} = \int_{0}^{2\pi} |\int_{0}^{t} \Lambda_{n}(x) dx| dt + O(1) \quad (n \to \infty)$$

thus, if we let

$$\lambda_n = \begin{cases} n , n = 2^k \\ o, n \neq 2^k \end{cases} \quad k = 0, 1, 2, \dots$$

then

$$\int_{0}^{2\pi} |A_{n}(t)| dt = \int_{0}^{2\pi} |\sum_{0}^{\log 2^{n}} 2^{k} \cos 2^{k} t| dt = O(n) \quad (n \to \infty).$$

Whereas,

$$\int_{0}^{2\pi} |\int_{0}^{t} \Lambda_{n}(x) dx| dt = \int_{0}^{2\pi} |\sum_{0}^{\lfloor \log 2^{n} \rfloor} \sin 2^{k} t| dt$$

and it follows from a theorem of Helson [6] that

$$\int_{0}^{2\pi} | \int_{0}^{t} \Lambda_{n}(x) dx | dt \neq O(1) \quad (n \to \infty).$$

In section 4, we shall examine sufficient conditions for  $(\lambda_k)$  to be in  $(c_{\omega}, C_F)$ . First we shall obtain the result analogous to that of Bojanic. In particular, using the necessary condition given in Section 3, we shall prove that if  $(\lambda_k)$  is a Stieltjes sequence then  $(\lambda_k) \in (c_{\omega}, C_F)$  if and only if

$$\omega\left(\frac{1}{n}\right)\int_{0}^{2\pi}|\Lambda_{n}(t)|dt = O(1) \quad (N \to \infty)$$

— 179 —

Finally, we shall give a sufficient condition for  $(\lambda_k)$  to be in  $(c_{\omega}, C_F)$  with no restrictions on  $(\lambda_k)$ . We shall show that  $(\lambda_k) \in (c_{\omega}, C_F)$  if

(1.5) 
$$\omega(\mu_n) \int_{0}^{2\pi} |\Lambda_n(t)| dt = O(1)$$

where

$$\mu_{n} = \frac{\int_{0}^{2\pi} |\int_{0}^{t} \Lambda_{n}(x) dx| dt}{\int_{0}^{2\pi} |\Lambda_{n}(t)| dt}$$

This condition is also necessary in the case that  $\omega(h) = O(h) (h \rightarrow 0)$ . However, it is generally not necessary. For example, if F(x) is the classical Lebesgue function (see [7, p. 195]), then  $F(x) - \frac{x}{2\pi}$  is continuous, of bounded variation, and its Fourier coefficients are not  $o\left(\frac{1}{n}\right)(n\rightarrow\infty)$ . Thus, if  $(\lambda_k)$  is the sequence of Fourier-Stieljes coefficients of  $d\left(F(t) - \frac{t}{2\pi}\right)$  we have using the theorem of Dirichlet-Jordan [7, p. 57] that

$$\lim_{n \to \infty} \int_{0}^{2\pi} \left| \sum_{0}^{n} \frac{\lambda_{k}}{k} \sin kt \right| dt = \int_{0}^{2\pi} \left| F(t) - \frac{t}{2\pi} \right| dt > 0.$$

while by the result of Helson [6]

$$\int_{0}^{2\pi} |\sum_{0}^{n} \lambda_{k} \cos kt| dt \neq O(1) \quad (n \to \infty)$$

Also,

$$\int_{0}^{2\pi} |\sum_{0}^{n} \lambda_{k} \cos kt| dt = O(\log n) \quad (n \to \infty)$$

since it is a Fourier-Stieljes series. So that, if we choose  $\omega$  to satisfy the conditions

$$\omega\left(\frac{1}{n}\right)\int_{0}^{2\pi} |\sum_{0}^{n} \lambda_{k} \cos kt| dt = O(1) \quad (n \to \infty)$$

and

$$\omega(\mu_n) \int_0^{2\pi} |\sum_{k=0}^n \lambda_k \cos kt| dt \neq O(1) \quad (n \to \infty)$$

with

$$\mu_n = \frac{\int\limits_0^{2\pi} |\sum\limits_0^{2n} \frac{\lambda_k}{k} \sin kt| dt}{\int\limits_0^{2\pi} \sum\limits_0^{n} \lambda_k \cos kt| dt}$$

we see that (1.5) is in general not necessary.

Although, we give necessary and sufficient conditions for  $(\lambda_k)$  to be in  $(c_{\omega}, C_F)$  in the case that  $(\lambda_k)$  is quasi-convex or a Stieljes sequence in general no conditions that are both necessary and sufficient are known.

2. Quasi-convex sequences. We consider first the simplest case of quasi convex sequences. If we apply Abel summation twice we find

$$\Lambda_{n}(t) = \sum_{0}^{n} (k+1) \Delta^{2} \lambda_{k} F_{k}(t) + n \Delta \lambda_{n-1} F_{n}(t) + \lambda_{n} D_{n}(t)$$

where  $D_n$  is the Dirichlet kernel

$$D_n(t) = \frac{1}{2\pi} \frac{\sin\left((n + \frac{1}{2})t\right)}{\sin\frac{1}{2}t} \, .$$

From the quasi-convexity and the fact that  $\int_{0}^{2\pi} |F_n(t)| dt = 1$ , we have

$$|||\sum_{0}^{n} (k+1) \Delta^{2} \lambda_{k} F_{k}|||_{\omega} \leq \int_{0}^{2\pi} |\sum (k+1) \Delta^{2} \lambda_{k} F_{k}(t)| dt = O(1) \quad (n \to \infty)$$

for any modulus of continuity  $\omega$ . Thus

$$(2.1) \qquad ||| \Lambda_n |||_{\omega} = O(1) + ||| n \Delta \lambda_{n-1} F_n + \lambda_n D_n |||_{\omega} \qquad (n \to \infty)$$

It follows from standard estimates that there exist positive constants  $C_1, C_2$  such that

(2.2) 
$$C_1 \omega \left(\frac{1}{n}\right) \log n \leq ||| D_n |||_{\omega} \leq C_2 \omega \left(\frac{1}{n}\right) \log n.$$

This result is contained in theorems (3.1) and (4.1) so we shall not supply an independent proof.

The main result of this section is

THEOREM 2.1. If  $(\lambda_k)$  is a quasi-convex sequence then  $(\lambda_k) \in (c_{\omega}, C_F)$  if and only if

(2.1) 
$$\lambda_n \omega \left(\frac{1}{n}\right) \log n = O(1) \quad (n \to \infty).$$

Proof: We first consider the case when  $(\lambda_n)$  is a bounded sequence. Then by a result of Tomic [3]

$$n\,\Delta\,\lambda_{n-1} = o\left(1\right).$$

Thus from (2.1) we have

$$||| \Lambda_n |||_{\omega} = O(1) + ||| \lambda_n D_n |||_{\omega}$$

and the theorem follows immediately from the inequalities (2.2).

We shall now show that the case  $(\lambda_k)$  unbounded does not arise. Tomić [3] has shown that if  $(\lambda_k)$  is quasi convex and unbounded then

(2.3) 
$$\lambda_n = An + B + o(1) \quad (n \to \infty)$$

and

(2.4) 
$$n \Delta \lambda_{n-1} = -An + o\left(\frac{1}{n}\right). \quad (n \to \infty)$$

thus if

$$\lambda_n \omega \left(\frac{1}{n}\right) \log n = O(1) \quad (n \to \infty)$$

we must have

$$\frac{\lambda_n}{n}\log n = O(1) \quad (n \to \infty)$$

and therefor  $(\lambda_n)$  cannot satisfy (2.3) and the conditions (2.1) and  $(\lambda_k)$  unbounded are not compatible. Secondly, if  $(\lambda_k)$  is unbounded then by virtue of (2.1)

$$||| \Lambda_{n} |||_{\omega} = O(1) + ||| n \Delta \lambda_{n-1} F_{n} + \lambda_{n} D_{n} |||_{\omega}$$

and thus by (2.2) (2.3), and (2.4) we must have

(2.5) 
$$||| \Lambda_n |||_{\omega} \ge An - A C_2 n \omega \left(\frac{1}{n}\right) \log n.$$

For  $\omega(h) = h$ , (2.5) fails and thus  $(\lambda_k) \notin (c_{\omega}, C_F)$  for any  $\omega$ . Thus,  $(\lambda_k)$  unbounded and  $(\lambda_k) \in (c_{\omega}, C_F)$  are also incompatible.

3. A necessary condition for  $(\lambda_k)$  to be in  $(c_{\omega}, C_F)$ . In this section, we shall give a necessary condition for  $(\lambda_k)$  to be in  $(c_{\omega}, C_F)$ . Our main result is the following theorem.

THEOREM 3.1. There exists an absolute constant C>0 such that for any trigonometric polynomial T of degree n we have

$$|||T|||_{\omega} \ge C\omega \left(\frac{1}{n}\right) \int_{0}^{2\pi} |T| dt \qquad n = 1, 2, \dots$$

An immediate corollary of this theorem and Proposition 1 is

COROLLARY 3.1. A necessary condition for the sequence  $(\lambda_k)$  to be in  $(c_{\omega}, C_F)$  is that

$$\omega\left(\frac{1}{n}\right)\int_{0}^{2\pi} |A_{n}| dt = O(1), \quad (n \to \infty)$$

We shall need some preliminary results concerning representations of trigonometric polynomials. Let  $x_k = \frac{2k\pi}{3n}$ , k = 0, 1, 2, ..., 3n-1. Then if T is a trigonometric polynomial of degree n, we have (see [8, p. 33])

(3.1) 
$$T(x) = \frac{2}{3n} \sum_{k=0}^{3n-1} T(x_k) K_n(x-x_k)$$

where

(3.2) 
$$K_n(t) = \frac{1}{\pi} \frac{\sin\left(\frac{3n}{2}t\right) \sin\left(\frac{n}{2}t\right)}{2n \left(\sin\frac{t}{2}\right)^2}$$

Also [8, p. 33] (3.3)  $\int_{0}^{2\pi} |T(x)| dx \leq \frac{1}{n} \sum_{0}^{3n-1} |T(x_{k})|.$ 

Now to the proof of theorem (3.1). Let  $0 < \delta < \frac{1}{4}$ . We wish to estimate

$$\frac{\int_{-\pi\delta}^{\pi\delta}}{\int_{3\pi}^{\pi\delta}} K_n(t) dt$$

— 183 —

from below. We have for  $|t| \leq \frac{\pi \delta}{3n}$ 

$$K_n(t) \ge \frac{1}{\pi} \left( \frac{\left(\frac{2}{\pi}\right) \left(\frac{3nt}{2}\right) \left(\frac{2}{\pi}\right) \left(\frac{nt}{2}\right)}{2n \left(\frac{t}{2}\right)^2} \right) = \frac{6}{\pi^3} n.$$

So that,

(3.4) 
$$\int_{\frac{-\pi\delta}{3n}}^{\overline{3n}} K_n(t) dt \ge \frac{6n}{\pi^3} \cdot \frac{2\pi\delta}{3n} = \frac{4}{\pi^2} \delta.$$

δπ

$$x_k + \frac{2\pi\delta}{3n}$$

Secondly, for  $k \neq 0$  we estimate  $\int K_n(t) dt$  from above. For  $x_k - \frac{\pi}{3n}$ 

$$\left|t-x_{k}\right| \leq \frac{2\pi \delta}{3n}$$
, we have

$$K_{n}(t) \leq \frac{\sin\frac{\delta\pi}{2}}{2n\left(\frac{2\pi}{3n}(k-\frac{1}{2})\right)^{2}} \leq \frac{\delta\pi}{4n}\frac{1}{\left(\frac{2\pi}{3n}(k-\frac{1}{2})\right)^{2}} = \frac{9\delta}{8\pi}\frac{n}{(k-\frac{1}{2})^{2}}$$

Thus

(3.5) 
$$\begin{aligned} x_k + \frac{2\pi}{3n} \\ \int \\ x_k - \frac{2\pi\delta}{3n} \\ x_k - \frac{2\pi\delta}{3n} \end{aligned} | K_n(t) | dt &\leq \frac{4\delta\pi}{3n} \cdot \frac{9\delta}{8\pi} \frac{n}{(k - \frac{1}{2})^2} = \frac{3}{2} \frac{\delta^2}{(k - \frac{1}{2})^2} . \end{aligned}$$

Let  $g_{\delta}(x)$  be the  $2\pi$ -periodic continuous function which has the value one on the interval  $\left[\frac{-\pi\delta}{3n}, \frac{\pi\delta}{3n}\right]$  has the value zero on  $\left[-\pi, \pi\right] - \left[\frac{-2\pi\delta}{3n}, \frac{2\pi\delta}{3n}\right]$  and is linear on the intervals  $\left[\frac{-\pi\delta}{3n}, \frac{-\pi\delta}{3n}\right]$  and  $\left[\frac{\pi\delta}{3n}, \frac{2\pi\delta}{3n}\right]$ . The function

$$\overline{g}_{\delta}(x) = \omega \left(\frac{\delta \pi}{3n}\right) \sum_{k=0}^{3n-1} Sgn(T(x_k)) g_{\delta}(x-x_k)$$

is in  $C_{\omega}$  and  $||\bar{g}_{\delta}||_{\omega} \leq 1$ . Also,

$$T(x_k) \int_{0}^{2\pi} \bar{g}_{\delta}(x) K_n(x-x_k) dx \ge \omega \left(\frac{\delta\pi}{3n}\right) |T(x_k)| \int_{x_k-\frac{\pi\delta}{3n}}^{x_k+\frac{\pi\delta}{3n}} |K_n(x-x_k)| dx$$

$$-\omega\left(\frac{\delta\pi}{3n}\right)\mid T(x_k)\mid \sum_{\substack{j=0\\j\neq k}}^{3n-1} \int_{\substack{x_j+\frac{2\pi\delta}{3n}\\j\neq k}} \mid K_n(x-x_k)\mid dx$$

which by virtue of (3.4) and (3.5) is

$$\geq \omega \left(\frac{\delta \pi}{3n}\right) \mid T(x_k) \mid \left(\frac{4}{\pi^2} \,\delta \,- \frac{3}{2} \,\delta^2 \sum_{\substack{j=0\\j\neq k}}^{3n-1} \frac{1}{(j-k-\frac{1}{2})^2}\right)$$
$$\geq \omega \left(\frac{\delta \pi}{3n}\right) \mid T(x_k) \mid \left(\frac{4}{\pi^2} \,\delta \,- \frac{3}{2} \,\delta^2 \,\sum_{j=0}^{\infty} \frac{1}{(j-\frac{1}{2})^2}\right)$$

Thus if we choose  $\delta_0 > 0$  such that

$$\left(\frac{4}{\pi^2}\,\delta_0\,-\frac{3}{2}\,\delta_0^2\,\sum_{j=0}^\infty\,\frac{1}{(j-\frac{1}{2})^2}\right)\,=\,C_0\,>\,0$$

We have, using the elementary properties of a modulus of continuity that

$$T(x_k) \int_{0}^{2\pi} \bar{g}_{\delta_0}(x) K_n(x-x_k) dx \ge C\omega\left(\frac{1}{n}\right) |T(x_k)| \ k = 0, 1, 2, ..., 3n - 1$$

where C is an absolute positive constant. Finally,

$$\int_{0}^{2\pi} \bar{g}_{\delta_{o}}(x) T(x) dx = \frac{2}{3n} \sum_{k=0}^{3n-1} T(x_{k}) \int_{0}^{2\pi} \bar{g}_{\delta_{o}}(x) K_{n}(x-x_{k}) dx \ge$$
$$\geq C \omega \left(\frac{1}{3n}\right) \cdot \frac{2}{3n} \sum_{k=0}^{3n-1} |T(x_{k})|$$

which by virtue of (3.3.) is

$$\geq \frac{2}{3} C \omega \left(\frac{1}{n}\right) \int_{0}^{2\pi} |T(x)| dx.$$

- 185 -

Thus, using Proposition 2,

$$||| T_{n} |||_{\omega} \ge \int_{0}^{2\pi} \bar{g}_{\delta_{0}}(x) T(x) dx \ge \frac{2}{3} C \omega \left(\frac{1}{n}\right) \int_{0}^{2\pi} |T(x)| dx$$

and the theorem is proved.

4. Sufficient conditions for  $(\lambda_k)$  to be in  $(c_{\omega}, C_F)$ . We first establish the result analogous to that of Bojanic (1.3) and (1.4). The proof is essentially that of Haršiladze [9].

THEOREM 4. 1. If  $(\lambda_k)$  is a Stieljes sequence and if  $\omega \left(\frac{1}{n}\right) \int_{0}^{2\pi} |\Lambda_n(x)| dx = O(1) \quad (n \to \infty)$ 

then  $(\lambda_k) \in (c_{\omega}, C_F)$ .

Proof: Let  $V_n(f)$  be the de la Vallée Poussin sums of f

$$V_n(f) = \int_0^{2\pi} f(t) \left( 2F_{2n}(t-x) - F_n(t-x) \right) dt .$$

It is well known [10, p. 92] that

(4.1) 
$$||f - V_n(f)||_{\infty} \leq C \omega \left(f, \frac{1}{n}\right)$$

where C is a constant independent of f and n. Also if T is a trigonometric polynomial of degree n then

$$V_n(T) = T$$

Thus if  $f \in C_{\omega}$ ,  $||f||_{\omega} \leq 1$ 

$$\int_{0}^{2\pi} f(t) \Lambda_{n}(t-x) dt = \int_{0}^{2\pi} \left( f(t) - V_{n}(f)(t) \right) \Lambda_{n}(t-x) dt + \int_{0}^{2\pi} V_{n}(f)(t) \Lambda_{n}(t-x) dt.$$

We have

$$\int_{0}^{2\pi} \int_{0}^{2\pi} \left( 2F_{2n}(t) - F_{n}(t) \right) \Lambda_{n}(t-x) dt \, | \, dx \, = \, O(1) \quad (n \to \infty).$$

L'Enseignement mathém., t. XIV, fasc. 2.

— 186 —

Since  $(\lambda_k)$  is a Stieltjes sequence. Thus

$$\begin{aligned} &|| \int_{0}^{2\pi} f(t) \Lambda_{n}(t-x) dt ||_{\infty} \leq || \int_{0}^{2\pi} (f(t) - V_{n}(f)(t) (\Lambda_{n}(t-x) dt ||_{\infty} + \\ &+ ||f||_{\infty} \int_{0}^{2\pi} |\int_{0}^{2\pi} (2F_{2n}(t) - F_{n}(t) (\Lambda_{n}(t-x) dt | dx \leq \\ &\leq || \int_{0}^{2\pi} (f(t) - V_{n}(f)(t)) \Lambda_{n}(t-x) dt ||_{\infty} + O(1) \quad (n \to \infty) \end{aligned}$$

which by virtue of (4.1) is

$$\leq C \omega \left(\frac{1}{n}\right) \int_{0}^{2\pi} |\Lambda_n(t)| dt + O(1) \quad (n \to \infty).$$

As a corollary of theorem 4.1 and theorem 3.1, we have

COROLLARY 4.1. A Stieljes Sequence  $(\lambda_k)$  is in  $(c_{\omega}, C_F)$  if and only if

$$\omega\left(\frac{1}{n}\right)\int_{0}^{2\pi} |\Lambda_{n}(t)| dt = O(1) \quad (n \to \infty).$$

We shall now give a sufficient condition for  $(\lambda_k)$  to be in  $(c_{\omega}, C_F)$  which requires no special restriction on  $(\lambda_k)$ .

THEOREM 4.2. A sufficient condition for  $(\lambda_k)$  to be in  $(c_{\omega}, C_F)$  is that

(4.2) 
$$\omega(\mu_n) \int_0^{2\pi} |\Lambda_n(t)| dt = O(1) \quad (n \to \infty)$$

where

$$\mu_n = \frac{\int_{0}^{2\pi} |\int_{0}^{x} \Lambda_n(t) dt | dx}{\int_{0}^{2\pi} |\Lambda_n(t)| dt} n = 0, 1, 2, \dots$$

If  $\omega(h) = h$  then (4.2) is also necessary.

Proof: We consider first the case when  $\omega(h) = h$ . If  $f \in C_{\omega}$  with  $||f||_{\omega} \leq 1$  then

 $|f'(x)| \leq 1 a. e.$ 

So that

$$|\int_{0}^{2\pi} f(t) \Lambda_{n}(t-x) dt| = |\int_{0}^{2\pi} f'(t) \overline{\Lambda}_{n}(t-x) dt| \leq \int_{0}^{2\pi} |\overline{\Lambda}_{n}(t)| dt$$
  
with  $\overline{\Lambda}_{n}(t) = \int_{0}^{t} \Lambda_{n}(u) du$ .

Thus,

$$||| \Lambda_n |||_{\omega} \leq \int_0^{2\pi} |\overline{\Lambda}_n(t)| dt,$$

the function  $g(x) = \frac{1}{2\pi} sgn \int_{0}^{x} \Lambda_{n}(t) dt$  is in  $C_{\omega}$  and  $||g||_{\omega} \leq 1$ . Also

$$\int_{0}^{2\pi} g(t) \Lambda_n(t) dt = |g(2\pi) \Lambda_n(2\pi) - \int_{0}^{2\pi} |\overline{\Lambda}_n(t)| dt| \ge \int_{0}^{2\pi} |\overline{\Lambda}_n(t)| dt - \lambda_0.$$

Thus,

$$\int_{0}^{2\pi} |\overline{A}_{n}(t)| dt - \lambda_{0} \leq ||| A_{n} |||_{\omega} \leq \int_{0}^{2\pi} |\overline{A}_{n}(t)| dt \quad n = 1, 2, \dots$$

This shows that (4.2) is necessary and sufficient for  $(\lambda_k)$  to be in  $(c_{\omega}, C_F)$  if  $\omega(h) = h$ .

Finally in the general case, the inequality

$$||\int_{0}^{2\pi} f(t) \Lambda_n(t-x) dt ||_{\omega} \leq \omega(\mu_n) \int_{0}^{2\pi} |\Lambda_n(t)| dt$$

is a simple modification of Lemma 1 of [11] and we will not give its proof.
