# ON A NEW CLASS OF TOPOLOGICAL SPACES

Kiyoshi ISÉKI

*To the memory of Professor J. Karamata*

In this short Note, I shall define a new class of topological spaces.

Let  $R$  be a Hausdorff space (i.e.  $T_2$ -space).  $R$  is said to be *H-closed* if there is a point common to the closures of all sets of any collection of open sets with the finite intersection property. As is well known, a compact  $T_1$ -space is characterized by the condition: there exists a subbasis  $\Phi$  for the closed sets of  $R$  such that there is a point common to all sets of any collection of sets of  $\Phi$  having the finite intersection property.

On the other hand, a *H-closed* space is not characterized by replacing a subbasis in the condition above into an open basis. Therefore we shall consider the following condition on *an open basis*  $\Phi$  in  $R$ .

- (A) *There is a point common to the closures of all sets of any collection of  $\Phi$  with the finite intersection property.*

As shown by the following simple examples, a topological space satisfying the condition (A) defines a new class of topological spaces.

In any discrete space, we can take an open basis  $\Phi$  satisfying the condition (A). Any *H-closed* space (or compact space) has an open basis satisfying the condition (A). Further, an arbitrary product of  $T_2$ -spaces with the condition (A) is a  $T_2$ -space satisfying the condition (A). On the other hand, the space of all rational numbers is not a topological space with the condition (A).
