THE HYPER-KLOOSTERMAN SUM

by Lenard WEINSTEIN

1. INTRODUCTION

Deligne, [1], has recently proved the very deep theorem on the bound of the Hyper-Kloosterman sum. His estimate results from his solutions of the strong forms of the Weil conjectures.

The Hyper-Kloosterman sum is defined:

$$S(a_1, \dots, a_k; p) = \sum e\left(\frac{a_1x_1 + \dots + a_kx_k}{p}\right)$$

where a_1, \dots, a_k, α are non-zero elements of the odd prime field F_p , and the summation runs through the k variables $x_i \in F_p$ with the relation $\prod x_i = \alpha$.

Deligne has shown:

$$|S(a_1, \dots, a_k; p)| \leq k p^{\frac{k-1}{2}}.$$

Here, we prove the following generalization for the bound of the Hyper-Kloosterman sum. Define:

$$S(a_1, \dots, a_k; q) = \sum e\left(\frac{a_1x_1 + \dots + a_kx_k}{q}\right),$$

where a_1, \dots, a_k are arbitrary integers, q a positive integer, and the summation runs through the k variables $x_i, 0 < x_i \leq q, x_i$ relatively prime to q , with the relation $\prod x_i \equiv 1 \pmod{q}$.

We show:

THEOREM 1. *Let q be an odd positive integer. Then :*

$$|S(a_1, \dots, a_k; q)| \leq k^{v(q)} q^{\frac{k-1}{2}} (a_1, a_k, q)^{\frac{1}{2}} \dots (a_{k-1}, a_k, q)^{\frac{1}{2}}$$

where $v(q)$ is the number of different prime factors of q .

THEOREM 2. Let q be an even positive integer. Then :

$$|S(a_1, \dots, a_k; q)| \leq 2^{\frac{k+1}{2}} k^{v(q)} q^{\frac{k-1}{2}} (a_1, a_k, q)^{\frac{1}{2}} \dots (a_{k-1}, a_k, q)^{\frac{1}{2}}.$$

Estermann, [2], has dealt with the case of the Kloosterman sum.

2. LEMMAS

Lemma 1. Consider the congruence:

$$x^k \equiv a \pmod{p^m}$$

where k, m are positive integers, a is an integer, p a prime and $(a, p) = 1$. Then:

1. If $p > 2$, this congruence has at most k incongruent solutions mod p^m .
2. If $p = 2$ and k is odd, then this congruence has exactly 1 solution mod p^m .
3. If $p = 2$, and $k = 2^r l$, $r > 1$, l odd, then this congruence has at most $\min\{2^{r+1}, p^m\}$ solutions mod p^m .

Proof: This is essentially found on pp. 115, 119 of [3].

Lemma 2. Let p be a prime, and m, n positive integers, $\frac{1}{2}m \leq n < m$. Let $y_1, \dots, y_{k-1}, z_1, \dots, z_{k-1}$ be integers; $p \nmid y_1, \dots, p \nmid y_{k-1}$. Define $[y_1, \dots, y_{k-1}; p^m]$ as that integer y , $0 < y < p^m$ such that $y(y_1 \dots y_{k-1}) \equiv 1 \pmod{p^m}$. Then:

$$\begin{aligned} [y_1 + p^n z_1, \dots, y_{k-1} + p^n z_{k-1}; p^m] &\equiv [y_1, \dots, y_{k-1}; p^m] \\ &- [y_1; p^m]^2 [y_2; p^m] \dots [y_{k-1}; p^m] p^n z_1 \\ &\quad \cdot \\ &\quad \cdot \\ &\quad \cdot \\ &- [y_1; p^m] \dots [y_{k-2}; p^m] [y_{k-1}; p^m]^2 p^n z_{k-1} \pmod{p^m} \end{aligned}$$

Proof: This follows from the relation

$$[y_1; p^m] \dots [y_{k-1}; p^m] \equiv [y_1, \dots, y_{k-1}; p^m] \pmod{p^m}$$

and Lemma 1 of [2].
