also elliptic, the foot of the perpendicular from the fixed point of  $g$  onto the invariant line of  $g$  would be fixed by  $g$ , and this cannot be. If  $g$  was at the same time elliptic with fixed point  $a \in H^{n+1}$  and parabolic with fixed point  $b \in S^n$ , the line from  $a$  towards  $b$  would have two points at infinity  $b$  and  $b'$  both fixed by  $g$ , and this cannot be.

That any  $g \in GM(n)_0$  belongs to one of the three classes follows for example from Brouwer's fixed point theorem. (See also 4.9.3 in [Th].)  $\square$

Observe that an hyperbolic isometry  $g \in GM(n)_0$  has a unique invariant line  $\delta$ . Suppose indeed that there are two of them, say  $\delta$  and  $\delta'$ . If  $\delta \cap \delta' \neq \emptyset$ , the intersection point (which is unique) is fixed by  $g$ , and this cannot be. If  $\delta \cap \delta' = \emptyset$  and if  $\delta, \delta'$  have no common point at infinity, there is a unique line perpendicular to both  $\delta$  and  $\delta'$ ; but this line intersects  $\delta$  in a point fixed by  $g$ , and this cannot be. Assume finally that  $\delta \cap \delta' = \emptyset$  and that  $\delta$  and  $\delta'$  have a common point at infinity; choose some number  $\rho > 0$  and consider the set  $C_\rho$  of points in  $H^{n+1}$  at a distance of  $\rho$  from  $\delta'$ ; the intersection  $C_\rho \cap \delta$  is a point fixed by  $g$ , and again this cannot be. One may consequently also define an isometry  $g \in GM(n)_0$  to be

*elliptic* if  $d(a, g(a)) = 0$  for some  $a \in H^{n+1}$ ,

*parabolic* if  $\inf d(a, g(a)) = 0$ , with the infimum over  $a \in H^{n+1}$  not attained,

*hyperbolic* if  $\inf d(a, g(a)) > 0$  (and the infimum is then attained exactly on the invariant line of  $g$ ).

We shall need below the following *dynamical description*. An hyperbolic isometry  $g \in GM(n)_0$  has on  $S^n$  one attracting point  $P_a$  and one repulsing point  $P_r$ . This means that, for any neighborhood  $U$  of  $P_a$  in  $S^n$  and for any compact subset  $K$  of  $S^n - \{P_r\}$ , one has  $g^k(K) \subset U$  for  $k$  large enough. (And similarly with  $g^{-1}$  instead of  $g$  when exchanging  $P_a$  and  $P_r$ .) Consider now a parabolic isometry  $g \in GM(n)_0$  with fixed point  $P \in S^n$ . Let  $U$  be a neighborhood of  $P$  in  $S^n$  and let  $K$  be compact in  $S^n - \{P\}$ ; then  $g^k(K) \subset U$  for any  $k \in \mathbf{Z}$  with  $|k|$  large enough. (This is obvious when  $g$  is a translation in  $\mathbf{R}^n \times \mathbf{R}_+^*$  by some vector in  $\mathbf{R}^n$ , and any parabolic isometry of  $H^{n+1}$  is conjugate to such a translation.)

#### 4. FREE SUBGROUPS OF $GL(2, \mathbf{R})$ AND OF $GL(2, \mathbf{C})$

We show in this section that a subgroup of the proper Mœbius group  $G = PGL(2, \mathbf{R})$  which is not almost solvable contains free groups; the same fact for  $GL(2, \mathbf{R})$  follows straightforwardly. We discuss also the case of  $GL(2, \mathbf{C})$ .

**PROPOSITION.** *Let  $g, h \in G - \{1\}$  be without any common fixed point in  $H^2 \cup S^1$ . Then the group  $\Gamma$  generated by  $g$  and  $h$  contains free groups, up to two exceptions.*

*The first of these happens when  $g^2 = h^2 = 1$ . The second when one element is an involution, say  $g^2 = 1$ , when  $h$  is hyperbolic, and when  $g$  exchanges the two fixed points of  $h$  on  $S^1$ . In these two cases,  $\Gamma$  is the infinite dihedral group, and is thus solvable.*

*Proof.* We check below in each of the non exceptional cases that  $\Gamma$  contains a free group.

*Case 1.* One element, say  $g$ , is parabolic with fixed point  $P \in S^1$ .

Consider the parabolic  $k = hgh^{-1}$ , with fixed point  $Q = h(P) \neq P$  in  $S^1$ . Let  $S_1$  [respectively  $S_2$ ] be a compact neighborhood of  $P$  [resp.  $Q$ ] in  $S^1$  with  $S_1 \cap S_2 = \emptyset$ . The end of section 3 shows that there exists a positive integer  $n_0$  such that  $g^n(S_2) \subset S_1$  and  $k^n(S_1) \subset S_2$  for any  $n \in \mathbf{Z}$  with  $|n| \geq n_0$ . It follows from Klein's criterium that  $g^{n_0}$  and  $k^{n_0}$  generate a free subgroup of  $G$ .

*Case 2.* Both  $g$  and  $h$  are hyperbolic.

Let  $S_1$  [respectively  $S_2$ ] be a compact neighborhood of the fixed points of  $g$  [resp. of  $h$ ] in  $S^1$  with  $S_1 \cap S_2 = \emptyset$ , and proceed as in case 1.

*Case 3.* One of the elements, say  $h$ , is hyperbolic with fixed points  $P, Q \in S^1$  and  $g$  does not exchange them, say  $R = g(Q) \notin \{P, Q\}$ .

If  $g(P) \notin \{P, Q\}$  then  $h$  and  $ghg^{-1}$  are as in case 2. We may thus assume that  $g(P) = Q$ . If  $g(R) \neq P$  then  $h$  and  $g^2hg^{-2}$  are again as in case 2. We may thus also assume  $g(R) = P$ . Consider then  $h' = g^{-1}hg$ , an hyperbolic with fixed points  $R$  and  $P$ , as well as  $h'' = ghg^{-1}hgh^{-1}g^{-1}$ , an hyperbolic with fixed points  $Q = ghg^{-1}(Q)$  and  $S = ghg^{-1}(P)$ . One has  $h(R) \neq Q$  and thus  $S = gh(R) \neq g(Q) = R$ ; one has also  $h(R) \neq R$  and  $S \neq g(R) = P$ . Consequently  $h'$  and  $h''$  are as in case 2.

*Case 4.* Both  $g$  and  $h$  are elliptic with  $g^2 \neq 1$ .

Possibly after conjugation within  $G$ , one may assume that  $g = r_\alpha$  is a rotation around the origin of the disc  $H^2$  by some angle  $\alpha \in ]0, 2\pi[ - \{\pi\}$ . Then  $k = hgh^{-1} \neq g$ , otherwise  $h$  would also fix the origin.

In the average, any point of  $S^1$  is rotated by  $k$  of an angle  $\alpha$ . More precisely, if  $\tilde{k}: \mathbf{R} \rightarrow \mathbf{R}$  is the lifting of  $k$  to the universal covering of  $S^1$  with  $0 \leq \tilde{k}(0) < 1$ ,

then  $\lim_{n \rightarrow \infty} \frac{1}{n} (\tilde{k}^n(x) - x)$  exists for all  $x \in \mathbf{R}$  and this limit is  $\alpha$ . Moreover

$$\min_{x \in \mathbf{R}} (\tilde{k}(x) - x) \leq \alpha \leq \max_{x \in \mathbf{R}} (\tilde{k}(x) - x).$$

(See any exposition of the rotation number, for example chapter 17 in [CL] or section 1 in [Ka].) It follows that there exists  $P \in \mathbf{S}^1$  with  $k(P) = g(P)$ , so that  $g^{-1}k$  has a fixed point in  $\mathbf{S}^1$  and one of the previous cases applies.

*Exceptional cases.* If  $g^2 = h^2 = 1$ , then  $gh$  generate an infinite cyclic subgroup of index 2 in  $\Gamma$  and  $\Gamma$  is isomorphic to the infinite dihedral group. If  $h$  is hyperbolic and if  $g$  exchanges its fixed points, then  $ghg^{-1} = h^{-1}$  so that  $g^2 = (gh)^2 = 1$  and  $\Gamma$  is as in the previous case.

The proof is now complete.  $\square$

The proposition above is well known, and may essentially be found in any of the following papers: [LU1], [Md], [Ro] (see corollary 1). One should also mention Magnus' surveys [Ms1], [Ms2].

As two elements of  $G$  having a common fixed point in  $H^2 \cup \mathbf{S}^1$  generate a solvable subgroup, we have proved the 2-generators particular case of the following fact.

**THEOREM 1.** *A subgroup  $\Gamma$  of  $G = PGL(2, \mathbf{R})$  (or of  $GL(2, \mathbf{R})$ ) which is not solvable contains free groups.*

*Proof.* We assume that  $\Gamma$  does not contain free groups, and check that  $\Gamma$  is solvable. If  $\Gamma$  contains at least one parabolic isometry, this follows from case 1 of the proof above. If it contains at least one hyperbolic isometry, then all hyperbolics in  $\Gamma$  have a common fixed point (see case 2) and then either all elements in  $\Gamma$  have a common fixed point or  $\Gamma$  is dihedral (see case 3). Finally, if  $\Gamma$  is an elliptic group, it follows from case 4 that  $\Gamma$  is abelian.  $\square$

This covers in particular the case of Fuchsian groups. The next theorem covers that of Kleinian groups.

**THEOREM 2.** *Let  $\Gamma$  be a subgroup of  $SL(2, \mathbf{C})$  which is not solvable. Assume moreover that  $\Gamma$  is not relatively compact (or equivalently that  $\Gamma$  is not conjugate to a subgroup of the maximal compact subgroup  $SU(2)$  of  $SL(2, \mathbf{C})$ ). Then  $\Gamma$  contains free groups.*

*In particular, a discrete subgroup of  $PGL(2, \mathbf{C})$  which is not almost solvable contains free groups.*

*Proof.* The group  $\Gamma$  acts on  $\mathbf{C}^2$ ; as  $\Gamma$  is not solvable, the representation is irreducible. Easy arguments à la Burnside show that  $\Gamma$  does not contain elliptic elements only; indeed,  $\Gamma$  does contain a hyperbolic element (see [CG], or corollary 1.8 in [B]). The first statement follows now as theorem 1.

The second follows from this: a discrete subgroup of  $PGL(2, \mathbf{C})$  containing elliptic elements only is finite. Indeed, such a group is periodic. If  $\Gamma$  is a priori

known to be finitely generated, then  $\Gamma$  is finite by a theorem of Schur (§36 in [CR]) so that the hyperbolic subspace  $F(\Gamma) = \{x \in H^3 \mid \Gamma x = \{x\}\}$  is non empty. In general, to any finitely generated subgroup  $\Gamma_1$  of  $\Gamma$  corresponds a non empty subspace  $F_1 \subset H^n$ ; it is easy to check that  $F(\Gamma) = \bigcap F_1$  is non empty so that  $\Gamma$  lies in a compact subgroup of the Möbius group; it follows again that  $\Gamma$  is finite.  $\square$

Instead of the assumption of theorem 2, assume the following: there exists  $g \in \Gamma$  with two distinct eigenvalues of same modulus, say  $\mu_1 = \rho \exp(i\theta_1)$  and  $\mu_2 = \rho \exp(i\theta_2)$  where  $\rho, \theta_1, \theta_2 \in \mathbf{R}$  satisfy  $\rho > 0$  and  $\theta_1 \not\equiv \theta_2 \pmod{2\pi}$ , and there exists an automorphism  $\alpha$  of  $\mathbf{C}$  with  $|\alpha(\mu_1)| \neq |\alpha(\mu_2)|$ . Then  $\alpha$  induces an automorphism  $\tilde{\alpha}$  of  $GL(2, \mathbf{C})$  and the proof applies to  $\tilde{\alpha}(\Gamma)$ . But this procedure has its limits, because there exist complex numbers  $\mu$  (such as  $\frac{1}{5}(3+4i)$ , see the remark below) such that  $|\alpha(\mu)| = 1$  for any automorphism  $\alpha$  of  $\mathbf{C}$  but which are not roots of 1; then the argument above fails <sup>1)</sup> for example for  $g = \begin{pmatrix} \mu & 0 \\ 0 & \mu^{-1} \end{pmatrix}$ .

Something is true however: let  $k$  be a finitely generated field of characteristic 0, let  $\mu \in k - \{0\}$  and assume  $\mu$  is not a root of 1. Then there exists a locally compact field  $k'$  endowed with an absolute value  $\omega$  and there exists a homomorphism  $\sigma: k \rightarrow k'$  such that  $\omega(\sigma(\mu)) \neq 1$ ; this is lemma 4.1 of [T]. It follows that the argument above may be recuperated, but one has to consider other fields than subfields of  $\mathbf{C}$ .

For self-consistency, let us end with the announced remark. For any automorphism  $\alpha$  of  $\mathbf{C}$ , one has clearly

$$\left| \alpha\left(\frac{3+4i}{5}\right) \right| = \left| \frac{3 \pm 4i}{5} \right| = 1;$$

we check now that  $\frac{3+4i}{5}$  is not a root of one.

Let  $p, q$  be coprime integers and let  $\mu = \exp\left(i2\pi \frac{p}{q}\right)$  be a root of 1. Then  $\mu$  is an algebraic number of degree  $\varphi(q)$ , where  $\varphi$  is Euler's function. It follows that  $\cos\left(2\pi \frac{p}{q}\right)$  is an algebraic number of degree  $d \geq \frac{1}{2} \varphi(q)$ : because if  $F$  is a polynomial of degree  $d$  in  $Z[X]$  with  $F\left(\cos\left(2\pi \frac{p}{q}\right)\right) = 0$ , then  $\mu$  is a root of

<sup>1)</sup> This shows that one point on page 50 of [D] is incorrect.

$X^d F\left(\frac{1}{2}X + \frac{1}{2}X^{-1}\right)$ , which is of degree  $2d$  in  $Z[X]$ , so that  $2d \geq \varphi(q)$ . If  $q \in \{1, 2, 3, 4, 6\}$ , one checks easily that  $\exp\left(i2\pi \frac{p}{q}\right) \neq \frac{3+4i}{5}$ . If  $q = 5$  or if  $q \geq 7$ , then  $\varphi(q) > 2$  so that  $\cos\left(2\pi \frac{p}{q}\right)$  is not rational. Thus the root of unity  $\mu$  cannot be equal to  $\frac{3+4i}{5}$ .

### 5. SOME OTHER CASES OF TITS' THEOREM

Let  $n$  be an integer with  $n \geq 2$ .

Define a subgroup  $\Gamma$  of  $GL(n, \mathbf{C})$  [respectively of  $PGL(n, \mathbf{C})$ ] to be *irreducible* if any linear subspace of  $\mathbf{C}^n$  [resp. of  $P_{\mathbf{C}}^{n-1}$ ] invariant by  $\Gamma$  is trivial, and *not almost reducible* if any subgroup of  $\Gamma$  of finite index is irreducible. When referring to the Zariski topology on  $PGL(n, \mathbf{C})$ , we use below the letter  $Z$ .

*Reduction.* Tits' theorem for complex linear groups is equivalent to the following statements (one for each  $n \geq 2$ ):

Let  $\Gamma$  be a subgroup of  $PGL(n, \mathbf{C})$  which is not almost solvable. Assume that

- (i) is not almost reducible;
- (ii) the  $Z$ -closure  $G$  of  $\Gamma$  in  $PGL(n, \mathbf{C})$  is  $Z$ -connected. Then  $\Gamma$  contains free groups.

That one may assume (i) without loss of generality is an easy exercise on reducibility, and one may assume (ii) because the  $Z$ -closure of any subgroup of  $PGL(n, \mathbf{C})$  has finitely many  $Z$ -connected components. (The hypothesis of the reduced statement are redundant: (i) and (ii) imply by Lie's theorem that  $G$  is not solvable, so that  $\Gamma$  is not almost solvable!)

Now let  $g \in PGL(n, \mathbf{C})$  and choose a representative  $\tilde{g} \in GL(n, \mathbf{C})$  of  $g$ . Let us define  $g$  to be

- elliptic* if  $\tilde{g}$  is semi-simple with all eigenvalues of equal moduli,
- parabolic* if  $\tilde{g}$  is not semi-simple and has all its eigenvalues of equal moduli,
- hyperbolic* if  $\tilde{g}$  has at least two eigenvalues of distinct moduli.

These definitions are obviously independent on the choice of  $\tilde{g}$ . They generalize those of section 3 as follows from [Gr]. The meaning of "hyperbolic" fits with current use in dynamical systems theory (see e.g. definition 5.1 in [Sh]).

Let  $g$  be hyperbolic and let  $\tilde{g}$  be as above. Let  $\tilde{A}(g)$  [respectively  $\tilde{A}'(g)$ ] be the direct sum of the nilspaces of  $\tilde{g}$  corresponding to all eigenvalues of maximal modulus [resp. to all other eigenvalues] of  $\tilde{g}$ . Let  $A(g)$  [resp.  $A'(g)$ ] be the canonical image of  $\tilde{A}(g) - \{0\}$  [resp.  $\tilde{A}'(g) - \{0\}$ ] in  $\mathbf{P} = P_{\mathbf{C}}^{n-1}$ . Then  $A(g) \cap A'(g) = \emptyset$  and the smallest linear subspace of  $\mathbf{P}$  containing both  $A(g)$  and  $A'(g)$  is  $\mathbf{P}$  itself. Tits calls  $A(g)$  [resp.  $A(g^{-1})$ ] the *attracting space* [resp. *repulsing space*] of  $g$ . We say that  $g$  is *sharp* if  $A(g)$  is a point and that  $g$  is *very sharp* if both  $A(g)$  and  $A(g^{-1})$  are points. For each  $k \in \{1, 2, \dots, n-1\}$ , the fundamental representation of  $GL(n, \mathbf{C})$  in  $\wedge^k \mathbf{C}^n$  induces an injection

$$\lambda_k: PGL(n, \mathbf{C}) \rightarrow PGL(\binom{n}{k}, \mathbf{C});$$

as  $g$  is hyperbolic,  $\lambda_k(g)$  is sharp for some  $k$ . We also say that two hyperbolic elements  $g, h \in PGL(n, \mathbf{C})$  are in *general position* if

$$\begin{aligned} A(g) \cup A(g^{-1}) &\subset \mathbf{P} - \{A'(h) \cup A'(h^{-1})\} \\ A(h) \cup A(h^{-1}) &\subset \mathbf{P} - \{A'(g) \cup A'(g^{-1})\}. \end{aligned}$$

Observe that any hyperbolic element of  $PGL(2, \mathbf{C})$  is very sharp, and that two hyperbolic elements of  $PGL(2, \mathbf{C})$  are in general position if and only if they do not have any common fixed point on  $\mathbf{S}^2$ .

Recall that an element of  $PGL(n, \mathbf{C})$  is *semi-simple* if its inverse image in  $GL(n, \mathbf{C})$  contains diagonalisable matrices.

LEMMA 1. *Let  $\Gamma$  be an irreducible subgroup of  $PGL(n, \mathbf{C})$  having a  $Z$ -connected  $Z$ -closure. If  $\Gamma$  contains a sharp semi-simple element  $g$ , then  $\Gamma$  contains a very sharp element.*

*About the proof.* Let  $\tilde{g} \in GL(n, \mathbf{C})$  be some representative of  $g$  having an eigenvalue of "large" modulus and all other eigenvalues with moduli "near" 1. For suitable  $h, u \in \Gamma$  and for  $j \in \mathbf{N}$  large enough, one may hope that  $g^{-j}hg^jh^{-1}u$  has a representative in  $GL(n, \mathbf{C})$  with one eigenvalue of very large modulus (look at  $hg^jh^{-1}u$ ), one eigenvalue of very small modulus (look at  $g^{-j}$ ), and other eigenvalues of moduli "near" 1. Section 3 of [T] shows that this hope is realistic. (See also below, after the theorem.)  $\square$

LEMMA 2. *Let  $\Gamma$  be an irreducible subgroup of  $PGL(n, \mathbf{C})$  having a  $Z$ -connected  $Z$ -closure. If  $\Gamma$  contains a very sharp element, then  $\Gamma$  contains two very sharp elements in general position.*

*Proof.* Let  $P_1, P_2$  be two linear subspaces of  $\mathbf{P}$  with  $P_1 \neq \emptyset$  and  $P_2 \neq \mathbf{P}$ . Then  $\{x \in G \mid x(P_1) \not\subset P_2\}$  is obviously a  $Z$ -open subset of  $G$ . It is not empty:

Choose indeed  $p \in P_1$ ; then the subspace of  $\mathbf{P}$  spanned by the orbit  $Gp$  is stable under  $G$  and must therefore coincide with  $\mathbf{P}$ ; hence there exists  $x \in G$  with  $x(p) \notin P_2$  and, a fortiori,  $x(P_1) \not\subset P_2$ .

Let  $g$  be a very sharp element in  $\Gamma$ . It follows from above that

$$X = \left\{ x \in G \left| \begin{array}{l} A(g) \text{ and } A(g^{-1}) \text{ are not contained in any of } xA'(g), \\ xA'(g^{-1}), x^{-1}A'(g), x^{-1}A'(g^{-1}) \end{array} \right. \right\}$$

is a non empty  $Z$ -open subset of  $G$ . Let  $y \in X \cap \Gamma$ . Then  $g$  and  $ygy^{-1}$  are both very sharp and are in general position. □

For the next lemma, we choose as above  $k$  with  $1 \leq k \leq n-1$  and we consider the  $k^{\text{th}}$  fundamental representation  $\lambda_k: SL(n, \mathbf{C}) \rightarrow SL(\binom{n}{k}, \mathbf{C})$  of  $SL(n, \mathbf{C})$ .

LEMMA. *Let  $\Gamma$  be a group and let  $\rho: \Gamma \rightarrow SL(n, \mathbf{C})$  be an irreducible representation. Then the  $Z$ -closure  $G$  of  $\rho(\Gamma)$  in  $SL(n, \mathbf{C})$  is semi-simple and the representation  $\sigma = \lambda_k \rho: \Gamma \rightarrow SL(\binom{n}{k}, \mathbf{C})$  is completely reducible.*

*Proof.* We show first that  $G$  is semi-simple. Consider the solvable radical  $R$  of  $G$ . By Lie's theorem, there exists an eigenvector for  $R$ , namely there exist  $v \in \mathbf{C}^n - \{0\}$  and  $\alpha \in \text{Hom}(R, \mathbf{C}^*)$  with  $r(v) = \alpha(r)v$  for all  $r \in R$ . As  $R$  is normal in  $G$ , any vector  $g(v)$  ( $g \in G$ ) is also an eigenvector for  $R$ . By irreducibility, any vector in  $\mathbf{C}^n$  is also an eigenvector, so that  $R$  is made up of dilations. But  $R$  is connected and is in  $SL(n, \mathbf{C})$ , so that  $R = 1$ .

Now  $\lambda_k: G \rightarrow SL(\binom{n}{k}, \mathbf{C})$  is completely reducible; denote by  $\lambda_{k,j}: G \rightarrow SL(W_j)$  the components of a decomposition  $\lambda_k = \bigoplus_{j \in J} \lambda_{k,j}$  and define  $\sigma_j = \lambda_{k,j} \rho$  ( $j \in J$ ). One has clearly  $\sigma = \bigoplus_{j \in J} \sigma_j$ , and each  $\sigma_j: \Gamma \rightarrow SL(W_j)$  is irreducible (this because  $\lambda_{k,j}$  is irreducible and by Schur's lemma). □

THEOREM. *Let  $\Gamma$  be a subgroup of  $PGL(n, \mathbf{C})$  and assume*

- (i)  $\Gamma$  is neither almost solvable nor almost reducible,
- (ii)  $\Gamma$  contains a semi-simple hyperbolic element.

*Then  $\Gamma$  contains free groups.*

*Proof.* As one may consider instead of  $\Gamma$  a subgroup of finite index, there is no loss of generality if we assume that the  $Z$ -closure of  $\Gamma$  is  $Z$ -connected. We denote by  $\tilde{\Gamma}$  the inverse image of  $\Gamma$  in  $SL(n, \mathbf{C})$ . By (ii), there exists  $k \in \{1, \dots, n-1\}$  and a semi-simple element  $\tilde{\gamma} \in \tilde{\Gamma}$  having eigenvalues  $\mu_1, \dots, \mu_n$  with  $|\mu_1| = \dots = |\mu_k| > |\mu_j|$  for  $j = k+1, \dots, n$ . Let  $N = \binom{n}{k}$ , and denote by  $\lambda_k$  both the fundamental representation  $GL(n, \mathbf{C}) \rightarrow GL(N, \mathbf{C})$  and the induced

homomorphism  $PGL(n, \mathbf{C}) \rightarrow PGL(N, \mathbf{C})$ . Then  $\lambda_k(\tilde{\gamma})$  has eigenvalues  $v_1, \dots, v_N$  with  $|v_1| > |v_j|$  for  $j = 2, \dots, N$ . By lemma 3, there exists a  $\lambda_k(\tilde{\Gamma})$ -irreducible subspace  $W_0$  of  $\mathbf{C}^N$ , associated to a representation  $\sigma_0: \tilde{\Gamma} \rightarrow GL(W_0)$ , such that  $v_1$  is an eigenvalue of  $\sigma_0(\tilde{\gamma})$ . As the  $Z$ -closure  $\tilde{G}$  of  $\tilde{\Gamma}$  in  $SL(n, \mathbf{C})$  is semi-simple, the group  $\tilde{G}$  is perfect and  $\sigma_0(\tilde{\Gamma})$  lies in  $SL(W_0)$ . As  $|v_1| > 1$ , one has  $\dim_{\mathbf{C}} W_0 \geq 2$ .

Thus one may assume from the start that  $\Gamma$  contains a sharp semi-simple element, and indeed by lemmas 1 and 2 two very sharp elements in general position. The conclusion follows as in case 2 of the proof of the proposition in section 4.  $\square$

Now lemma 1 remains true without the hypothesis "semi-simple". This has been announced by Y. Guivarch', who uses ideas of H. Fürstenberg to show the following: given an appropriate subset  $S$  of  $\Gamma$  containing a sharp element, then almost any "long" word in the letters of  $S$  is very sharp. Using this, one may replace (ii) in the theorem above by the following a priori weaker hypothesis

(ii')  $\Gamma$  is not relatively compact.

Then, one first checks as for theorem 2 of section 4 that  $\Gamma$  contains hyperbolic elements; one concludes as in the previous proof, with Guivarch's version of lemma 1.

For subgroups of  $PU(n)$ , one may repeat the discussion at the end of section 4.
